

# Question Answering

## Lecture 12

# Announcement

- Plan for the remainder of the course
  - Week 12 (today): QA + RAG
  - Week 13: RAG + Agent basics
  - Week 14: Review
- Homework:
  - HW4 release today --- regular homework
  - HW5: problem set
    - Gives you a feel of the final exam
  - ~~HW6~~:  $\max(\text{HW})$

# Modern QA from text

The common person's view? [From a novel]

“I like the Internet. Really, I do. Any time I need a piece of shareware or I want to find out the weather in Bogota ... I'm the first guy to get the modem humming. But **as a source of information, it sucks**. You got **a billion pieces of data**, struggling to be heard and seen and downloaded, and **anything I want to know seems to get trampled underfoot in the crowd.**”

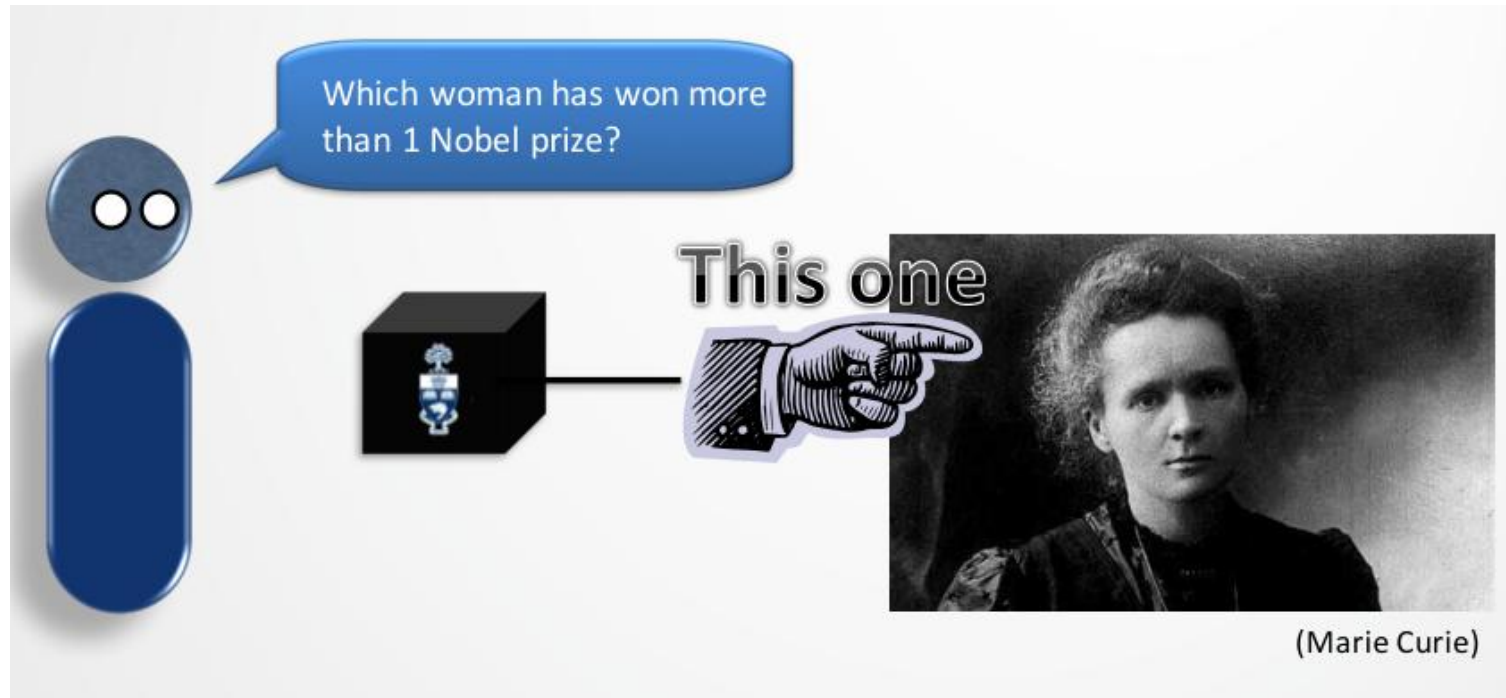

M. Marshall. The Straw Men. HarperCollins Publishers, 2002.

- An idea originating from the IR community.
- With massive collections of full-text documents, simply finding **relevant documents** is of limited use: we want **answers** from textbases.
- QA: give the user a (short) answer to their question, perhaps supported by evidence.

# Outline

- Intro to QA
- QA & IR before deep learning
- QA & IR with deep learning (BERT, dense retrieval...)
- RAG: QA with LLM

# Question Answering (QA)

- Question Answering (QA) usually involves a specific answer to a question.

# Information Retrieval (IR) and QA

A screenshot of a Google search results page for the query "which woman has won more than 1 nobel prize?". The search bar at the top shows the query. Below the search bar, there are tabs for "All", "Images", "News", "Videos", "Shopping", "Web", "Books", and "More". The "All" tab is selected. The search results are displayed in a list format. The first result is from Wikipedia, titled "List of female Nobel laureates", with a snippet mentioning Marie Curie. AI Overview

Marie Curie is the only woman to have won multiple Nobel Prizes, winning the Nobel Prize in Physics in 1903 and the Nobel Prize in Chemistry in 1911.

1903

Curie won the Nobel Prize in Physics with her husband, Pierre Curie, and Henri Becquerel for their work on radioactivity.

1911

Curie won the Nobel Prize in Chemistry for discovering the elements radium and polonium.

Curie's accomplishments are notable because...

One strategy is to turn QA into information retrieval (IR) and let the human complete the task.

# Question Answering (QA)

A screenshot of the WolframAlpha website. The header features the WolframAlpha logo with the tagline "computational knowledge engine". A search bar contains the query: "How much potassium is in 450,000 cubic kilometers of bananas?". Below the search bar, the "Input interpretation:" section shows the query broken down into components: "banana", "amount", "450 000 km<sup>3</sup> (cubic kilometers)", and "potassium". The "Result:" section displays the answer: "1.5 × 10<sup>12</sup> t (metric tons)".

WolframAlpha<sup>™</sup> computational knowledge engine

How much potassium is in 450,000 cubic kilometers of bananas?

Input interpretation:

|        |        |  |           |
|--------|--------|--|-----------|
| banana | amount | 450 000 km <sup>3</sup> (cubic kilometers) | potassium |
|--------|--------|--|-----------|

Result:

1.5 × 10<sup>12</sup> t (metric tons)

# Knowledge-based QA

1. Build a structured semantic representation of the query.
  - Extract times, dates, locations, entities using regular expressions.
  - Fit to well-known templates.
2. Query databases with these semantics.
  - Ontologies (Wikipedia infoboxes).
  - Restaurant review databases.
  - Calendars.
  - ...

# IR-based QA

# IR-based QA with LLM (RAG)

# Sample TREC questions

1. Who is the author of the book, "The Iron Lady: A Biography of Margaret Thatcher"?
2. What was the monetary value of the Nobel Peace Prize in 1989?
3. What does the Peugeot company manufacture?
4. How much did Mercury spend on advertising in 1993?
5. What is the name of the managing director of Apricot Computer?
6. Why did David Koresh ask the FBI for a word processor?
7. What debts did Quintex group leave?
8. What is the name of the rare neurological disease with symptoms such as: involuntary movements (tics), swearing, and incoherent vocalizations (grunts, shouts, etc.)?

# Query types

- Different kinds of questions can be asked.
  - Factoid questions, e.g.,
    - *How often were the peace talks in Ireland delayed or disrupted as a result of acts of violence?*
  - Narrative (open-ended) questions, e.g.
    - *Can you tell me about contemporary interest in the Greek philosophy of stoicism?*
  - Complex/hybrid questions, e.g.,
    - *Who was involved in the Schengen agreement to eliminate border controls in Western Europe and what did they hope to accomplish?*

# People **want** to ask questions...

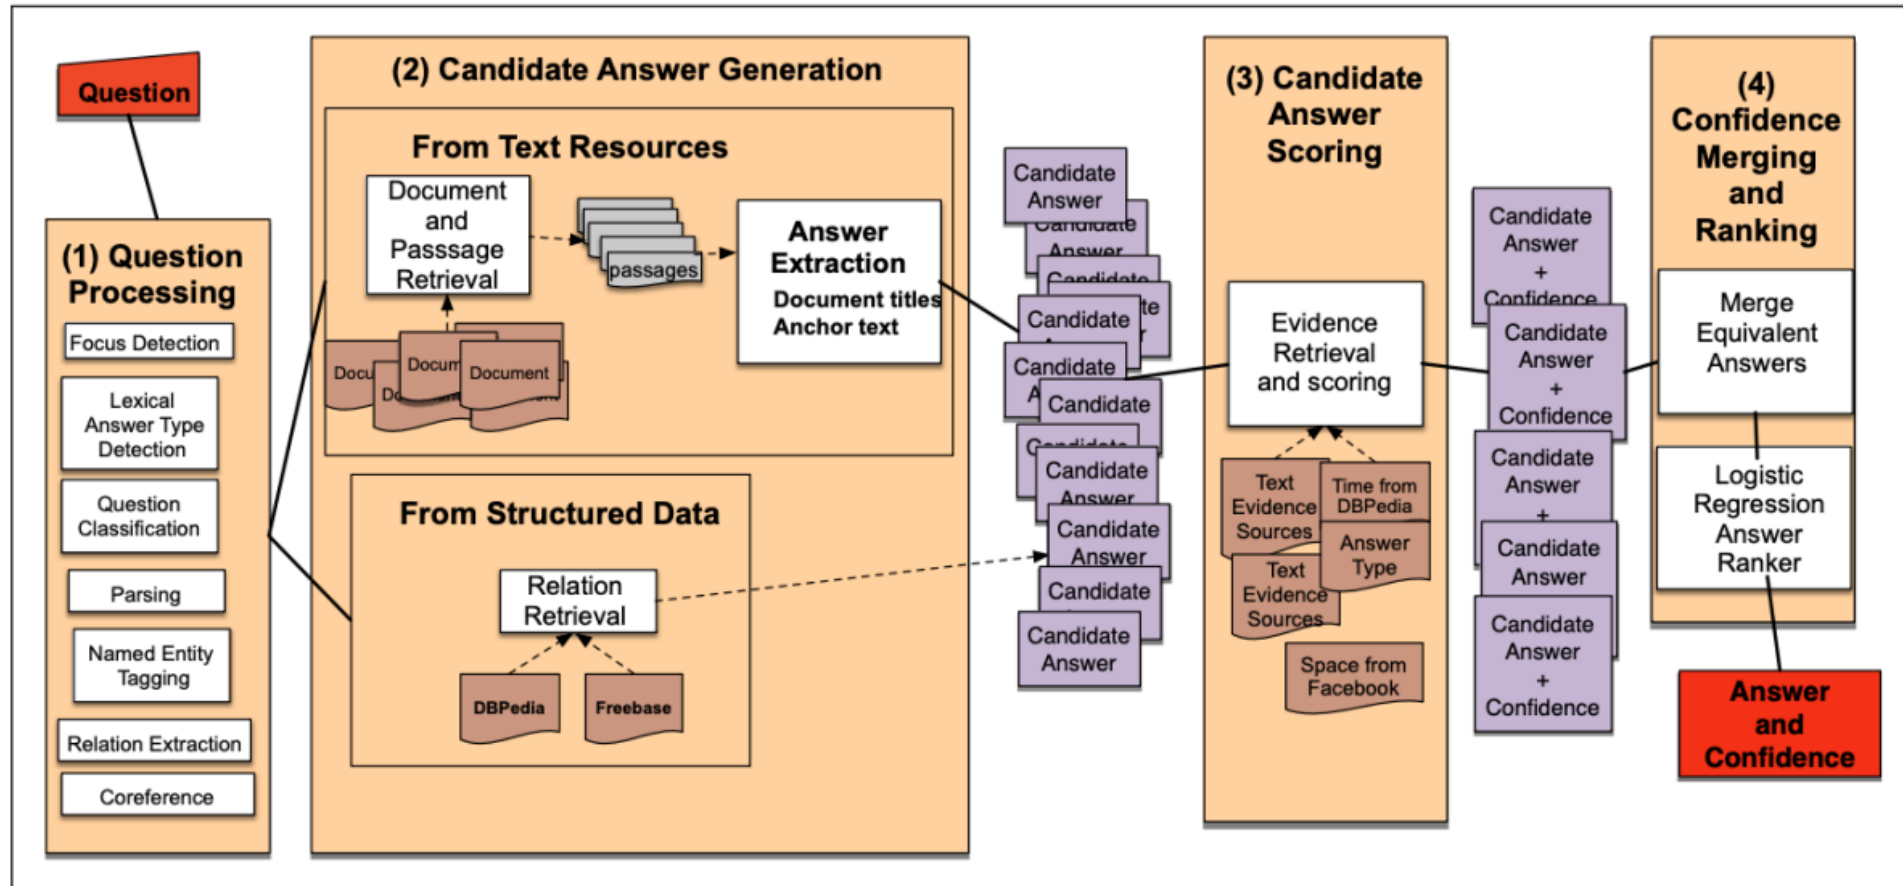

- **Examples from AltaVista query log (late 1990s)**
  - who invented surf music?
  - how to make stink bombs
  - where are the snowdens of yesteryear?
  - which english translation of the bible is used in official catholic liturgies?
  - how to do clayart
  - how to copy psx
  - how tall is the sears tower?
- **Examples from Excite query log (12/1999)**
  - how can i find someone in texas
  - where can i find information on puritan religion?
  - what are the 7 wonders of the world
  - how can i eliminate stress
  - What vacuum cleaner does Consumers Guide recommend

**Around 10% of early query logs are QUESTIONS.**

# 2011: IBM Watson beat Jeopardy! champions

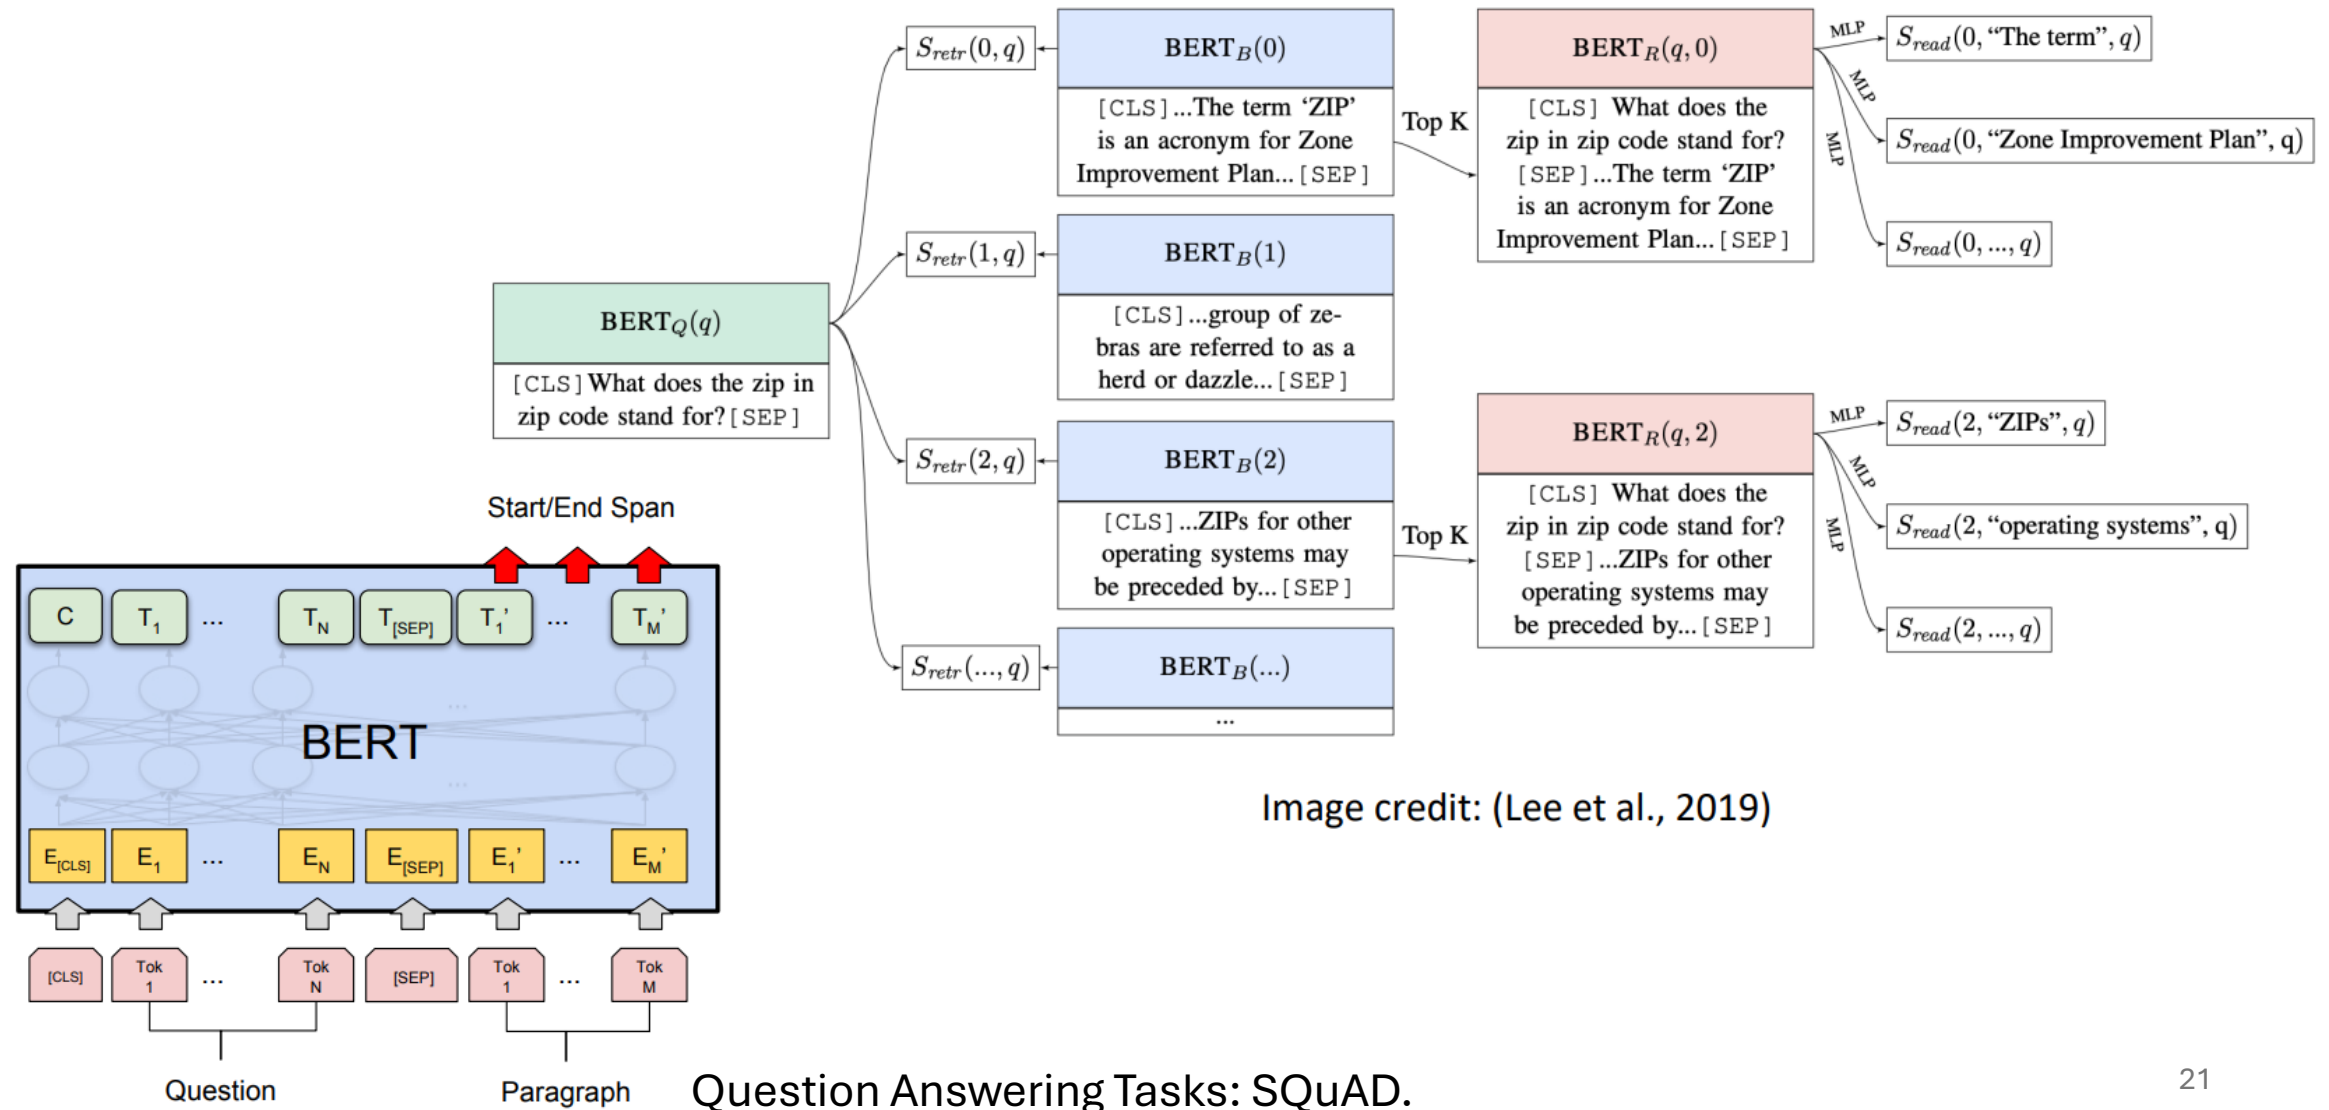

# IBM Watson: Search

# Not all problems are solved by these

- Where do lobsters like to live?
  - on a Canadian airline
- Where are zebras most likely found?
  - near dumps
  - in the dictionary
- Why can't ostriches fly?
  - Because of American economic sanctions
- What's the population of Mexico?
  - Three
- What can trigger an allergic reaction?
  - ..something that can **trigger** an allergic reaction

# Question answering in deep learning era

# SQuAD: Stanford question answering dataset

- 100k annotated (passage, question, answer) triples
  - Large-scale supervised datasets are also a key ingredient for training effective neural models for reading comprehension!
- Passages are selected from English Wikipedia, usually 100~150 words.
- Questions are crowd-sourced.
- Each answer is a short segment of text (or span) in the passage.
  - This is a limitation— not all the questions can be answered in this way!
- SQuAD was for years the most popular reading comprehension dataset; it is “almost solved” today (though the underlying task is not,) and the state-of-the-art exceeds the estimated human performance.
- SQuAD 2.0: some questions can’t be answered.

---

In meteorology, precipitation is any product of the condensation of atmospheric water vapor that falls under **gravity**. The main forms of precipitation include drizzle, rain, sleet, snow, **graupel** and hail... Precipitation forms as smaller droplets coalesce via collision with other rain drops or ice crystals **within a cloud**. Short, intense periods of rain in scattered locations are called “showers”.

What causes precipitation to fall?

**gravity**

What is another main form of precipitation besides drizzle, rain, snow, sleet and hail?

**graupel**

Where do water droplets collide with ice crystals to form precipitation?

**within a cloud**

<https://rajpurkar.github.io/SQuAD-explorer/>

# BERT for Reading Comprehension

$$p_{\text{start}}(i) = \text{softmax}(\mathbf{W}_s \mathbf{h}_i)$$

$$p_{\text{end}}(i) = \text{softmax}(\mathbf{W}_e \mathbf{h}_i)$$

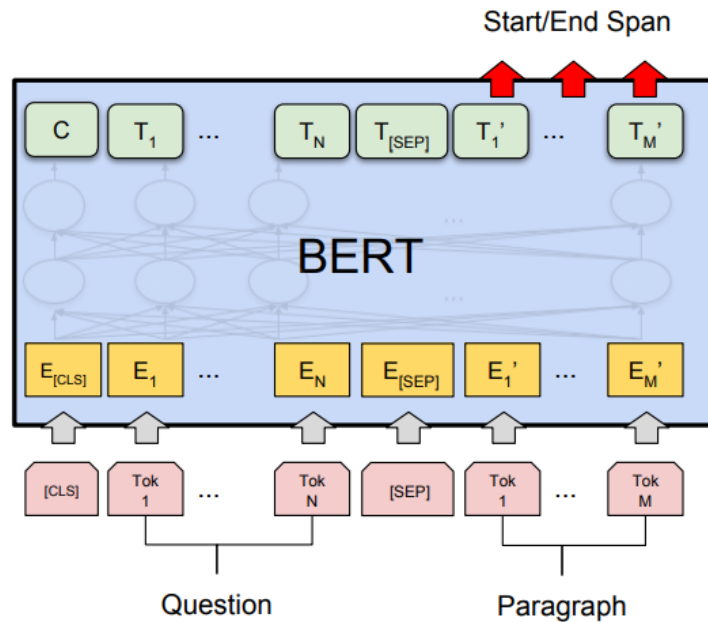

- This simplified version of QA aka **Reading Comprehension**.
  - (Passage, Question)  $\Rightarrow$  Answer

**Question:** How many parameters does BERT-large have?

**Reference Text:** BERT-large is really big... it has 24 layers and an embedding size of 1,024, for a total of 340M parameters! Altogether it is 1.34GB, so expect it to take a couple minutes to download to your Colab instance.

# BERT for Reading Comprehension

$$p_{\text{start}}(i) = \text{softmax}(\mathbf{W}_s \mathbf{h}_i)$$

$$p_{\text{end}}(i) = \text{softmax}(\mathbf{W}_e \mathbf{h}_i)$$

- This simplified version of QA aka **Reading Comprehension**.
  - (Passage, Question)  $\Rightarrow$  Answer

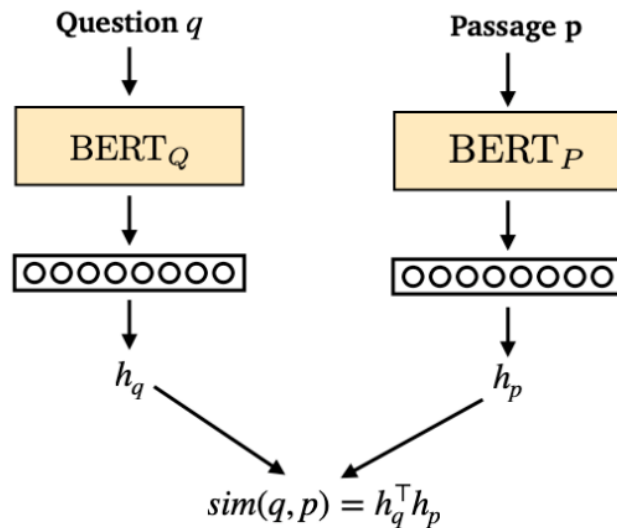

|                   | F1    | EM    |
|-------------------|-------|-------|

| BERT-base         | 88.5  | 80.8  |
| BERT-large        | 90.9  | 84.1  |
| XLNet             | 94.5  | 89.0  |
| RoBERTa           | 94.6  | 88.9  |
| ALBERT            | 94.8  | 89.3  |

# BERT for IR

- Dense passage retrieval (DPR)
  - We can also just train the retriever using question-answer pairs!

- Trainable retriever (using BERT) largely outperforms traditional IR retrieval models.

# Neural Methods for IR Beyond Re-ranking

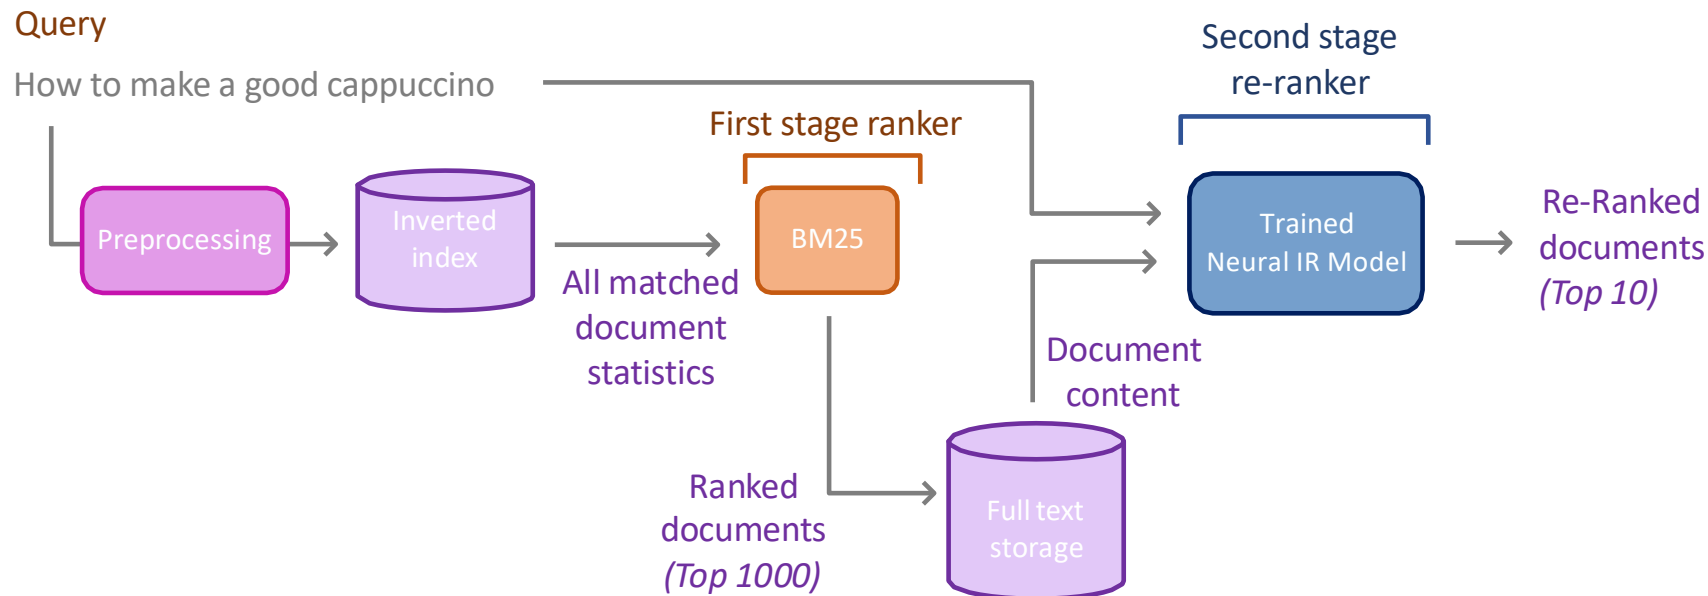

---

- Re-Ranking depends on a candidate selection (bottleneck)
  - How to bring neural advances in this first-stage phase
- Today we look at dense retrieval as (inverted index) BM25 alternative
- Many other neural approaches to improve first-stage retrieval:
  - **Doc2query**: Document expansion with query text that would semantically match the document. Exists in both BERT and T5 variants. Then index the expanded documents with BM25
  - **DeepCT**: Assign term weights based on BERT output during indexing -> retrieval with inverted index & BM25
  - **COIL**: Fuses contextual vectors into an inverted index structure, for faster lookup of semantic matches

# Neural Re-Ranking

---

- Re-rankers: They change the ranking of a pre-selected list of results
  - Same interface as classical ranking methods:  $\text{score}(q, d)$
- Query workflow:

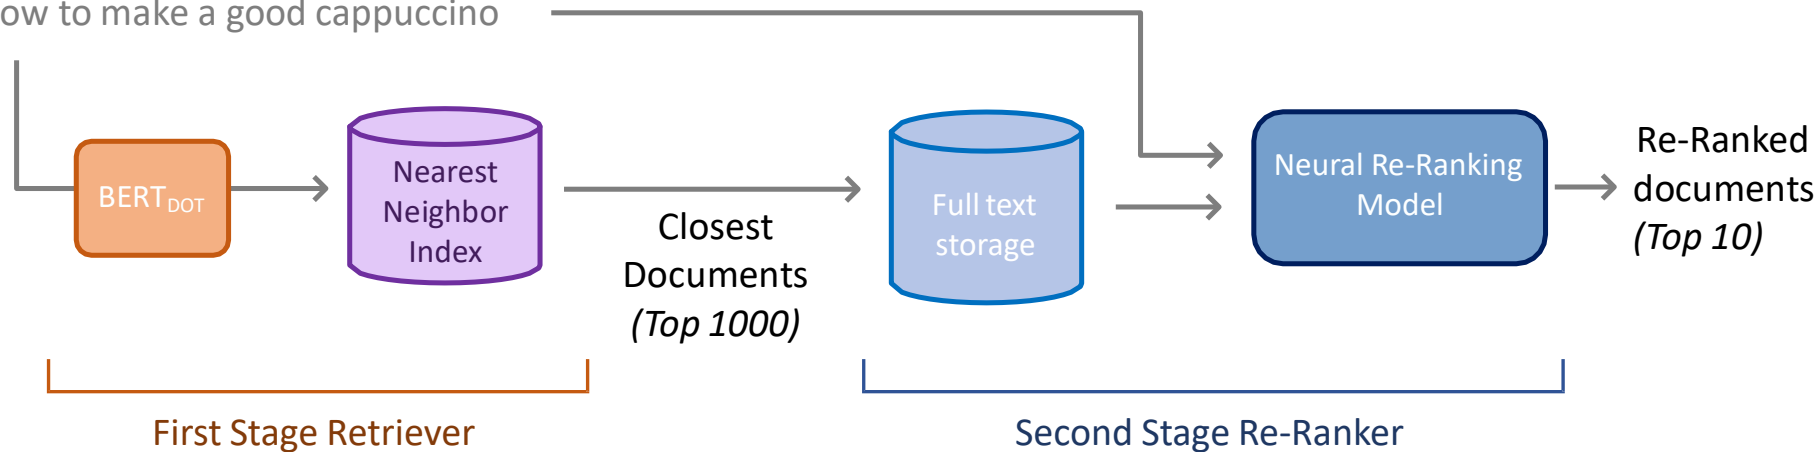

# Dense Retrieval (with Re-Ranking)

- Dense retrieval replaces the traditional first stage
  - Using a neural encoder & nearest neighbor vector index
  - Can be used as part of a larger pipeline

Query

How to make a good cappuccino

# Standalone Dense Retrieval

---

- If dense retrieval is effective enough for our goals:
  - We can also use it as a standalone solution
  - Much faster + less complexity if we remove re-ranking stage

Query

How to make a good cappuccino

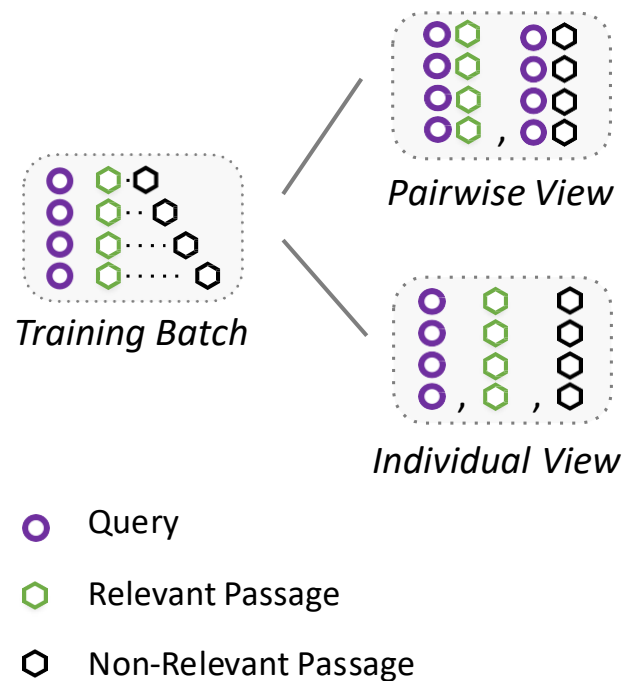

# Training

---

- Neural IR models are typically trained with triples (pairwise +,-)
  - Triple: 1 query, 1 relevant, 1 non-relevant document
  - Generate embeddings for query, relevant doc, non-relevant doc
  - Loss function: Maximize margin between rel/non-rel document
- All model components are trained end-to-end
  - Of course we could decide to freeze some parts for more efficient training

# Creating Training Batches

---

- We form a batch by sampling as many triples as is allowed by the GPU memory
  - Typical batch size: 16-128
  - We mix different queries together
  - Depending on the model we need to create query-passage pairs or run each of the three sequences individually through the model
- We run a backward pass & gradient update per batch
- Sequency inputs come as a single matrix, so we need to pad different length inputs

# Sampling Non-Relevant Passages

---

- Most collections only come with judgements of relevant (or false-positive selections from other models) and not truly non-relevant judgements
  - It doesn't make sense to spend resources annotating random pairs
- We need to tell the model what is non-relevant
  - Simple procedure to sample non-relevant passages:
    - Run BM25 and get the top-1000 results per training query and randomly select a few of those results as non-relevant
    - The non-relevant selections provide some signal (as there must be at least some lexical overlap)
    - But mostly non-relevant passages -> works pretty good in practice
    - A bit of noise is good (we don't know the degree of non-relevance, but that's ok)

# Loss Function

---

- Choice of different methods that aim to maximize the margin between rel & non-rel document

- Plain Margin Loss:

$$\text{loss} = \max(0, s_{\text{nonrel}} - s_{\text{rel}} + 1)$$

- Native support in PyTorch: `torch.nn.MarginRankingLoss()`

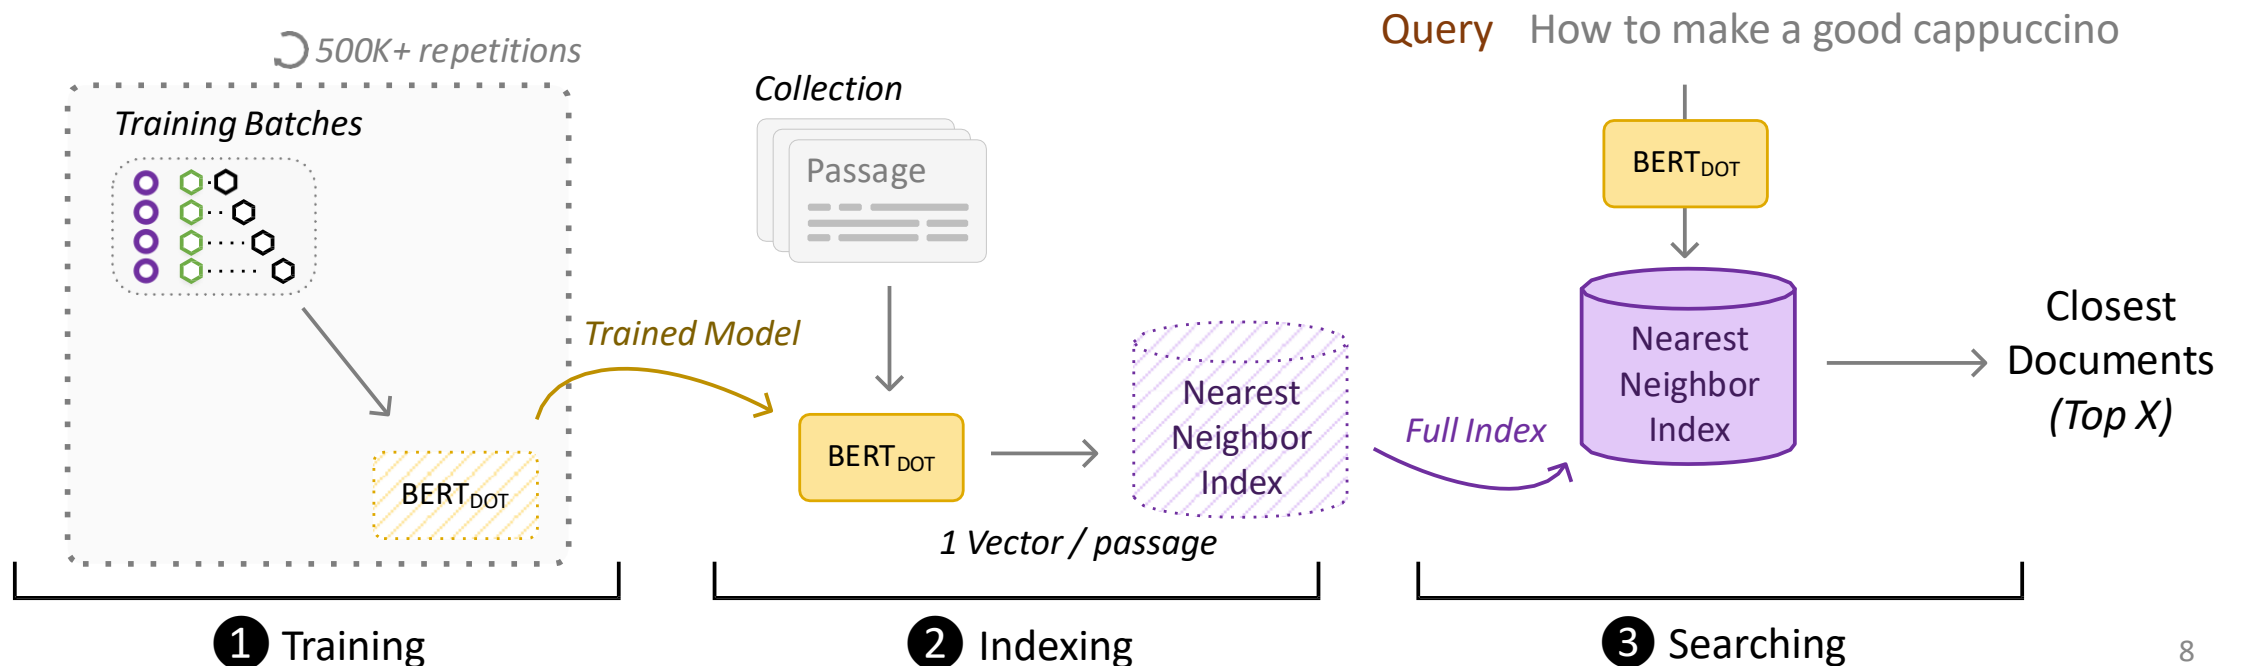

- RankNet:

$$\text{loss} = \text{BinaryCrossEntropy}(s_{\text{rel}} - s_{\text{nonrel}})$$

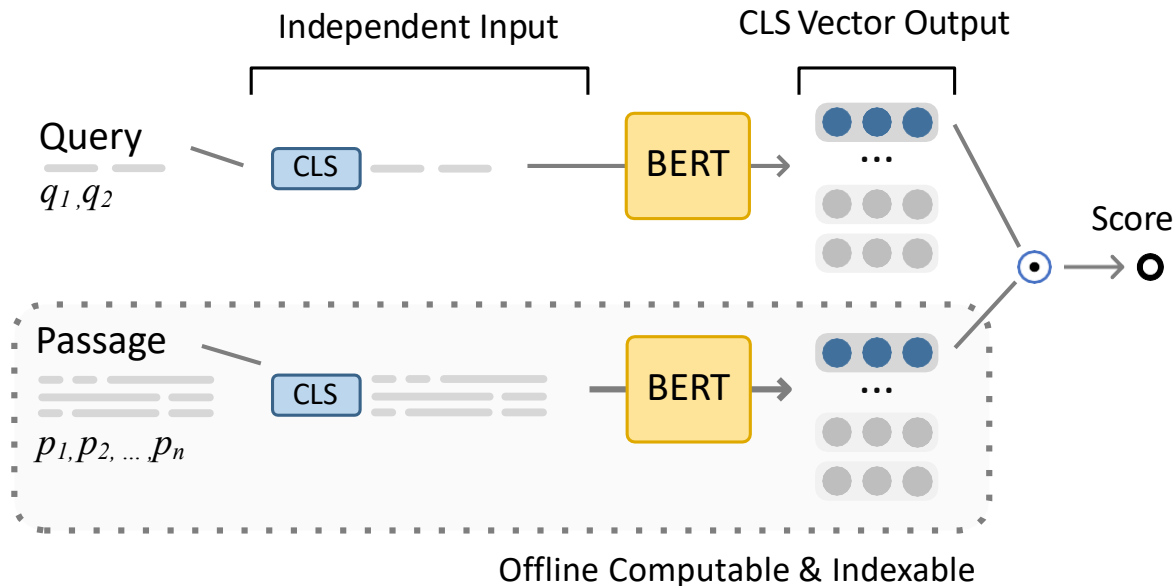

- Both losses assume binary relevance

# Dense Retrieval Lifecycle

- 3 major phases in the dense retrieval lifecycle
  - Each comes with several complex choices and required techniques
  - Could skip ❶ if we use a pre-trained model

# BERT<sub>DOT</sub> Model

- Passages and queries are compressed into a single vector
  - Passages are completely independent -> moves most computation into the indexing phase
  - Only need query encoding at runtime
- Relevance is scored with a dot-product
  - Cosine-sim variants also exist
  - This allows easy use of an (approximate) nearest neighbor index

# BERT<sub>DOT</sub>

- Simple formula (as long as we abstract BERT):

Encoding

$$\begin{aligned}\hat{q} &= \text{BERT}([CLS]; q_{1..n})_{CLS} \\ \hat{p} &= \text{BERT}([CLS]; p_{1..m})_{CLS}\end{aligned}$$

Independent computation

Matching

$$s = \hat{q} \cdot \hat{p}$$

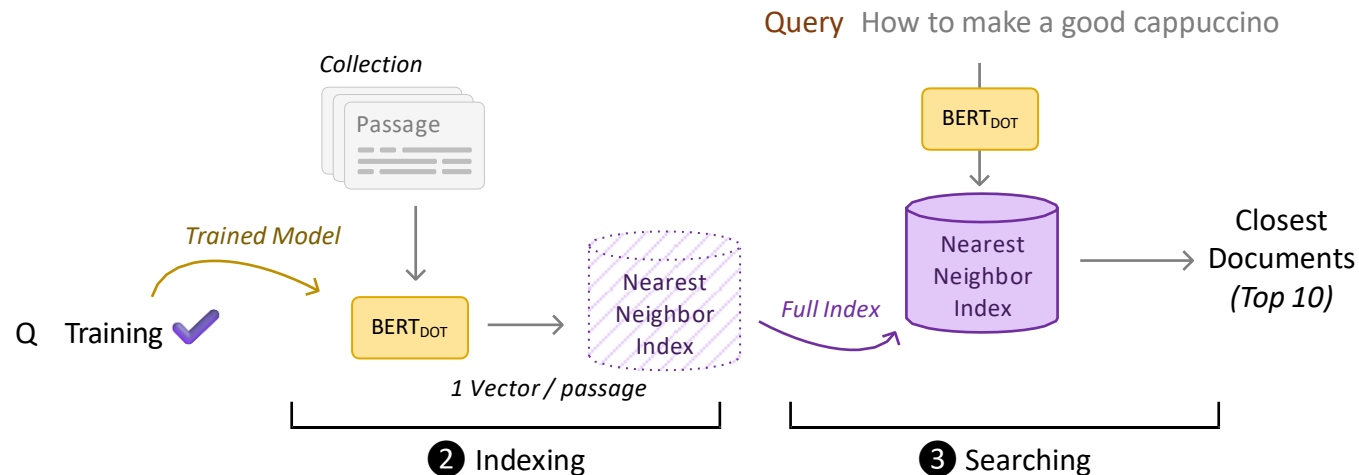

Can be done “outside” the model  
(with a nearest neighbor library)

- Optional compression of  $\hat{q}$ ,  $\hat{p}$  with a single linear layer (to reduce dimensionality)

|            |                        |
|------------|------------------------|
| $q_{1..n}$ | Query tokens           |
| $p_{1..m}$ | Passage tokens         |
| BERT       | Pre-trained BERT model |
| [CLS]      | Special tokens         |
| $x_{CLS}$  | Pool the CLS vector    |
| $s$        | Output score           |

# Nearest Neighbor Search

- Once we have a trained DR model, we encode every passage in our collection
  - We save passages in an (approximate) nearest neighbor index
- During search we encode the query on the fly and search for nearest neighbor vectors in the passage index

# NN Search: GPU Brute-Force

---

- Retrieving the top-1K from 9 million vectors is fast
  - We need to do 9M dot-products (a very big matrix multiplication) with 768 dim. vectors
- GPUs are made for this
  - Vectors must fit in GPU memory
  - 70ms latency / query
  - Incredible scale when increasing the batch size
  - Using a CPU this takes ~1 sec. / q

**Table 1: Latency analysis of Top-1000 retrieval using our BERT<sub>DOT</sub> retrieval setup for all MSMARCO passages using DistilBERT and Faiss (FlatIP) on a single Titan RTX GPU**

| Batch Size   | Q. Encoding |                       | Faiss Retrieval |                       | Total    |                       |
|--------------|-------------|-----------------------|-----------------|-----------------------|----------|-----------------------|
|              | Avg.        | 99 <sup>th</sup> Per. | Avg.            | 99 <sup>th</sup> Per. | Avg.     | 99 <sup>th</sup> Per. |
| <b>1</b>     | 8 ms        | 11 ms                 | 54 ms           | 55 ms                 | 64 ms    | 68 ms                 |
| <b>10</b>    | 8 ms        | 9 ms                  | 141 ms          | 144 ms                | 162 ms   | 176 ms                |
| <b>2,000</b> | 273 ms      | 329 ms                | 2,515 ms        | 2,524 ms              | 4,780 ms | 4,877 ms              |

Efficiently Teaching an Effective Dense Retriever with Balanced Topic Aware Sampling; Hofstätter et al. SIGIR 2021  
<https://arxiv.org/abs/2104.06967>

# Indexing Techniques: Flat Index

---

Flat Index = Brute Force

- No additional processing, using raw vector embeddings
- Calculates distance for each pair, slow
- Exhaustive search, best accuracy

# Indexing Techniques: Inverted File Index (IVF)

---

Partition the dataset into clusters

- Use clustering algorithm (e.g. k-means) to divide into k clusters
- Compute the centroids of each cluster
- For each cluster, store:
  - The centroid vector
  - An inverted index list of the vectors assigned to that cluster

# Indexing Techniques: Inverted File Index (IVF)

---

Query time:

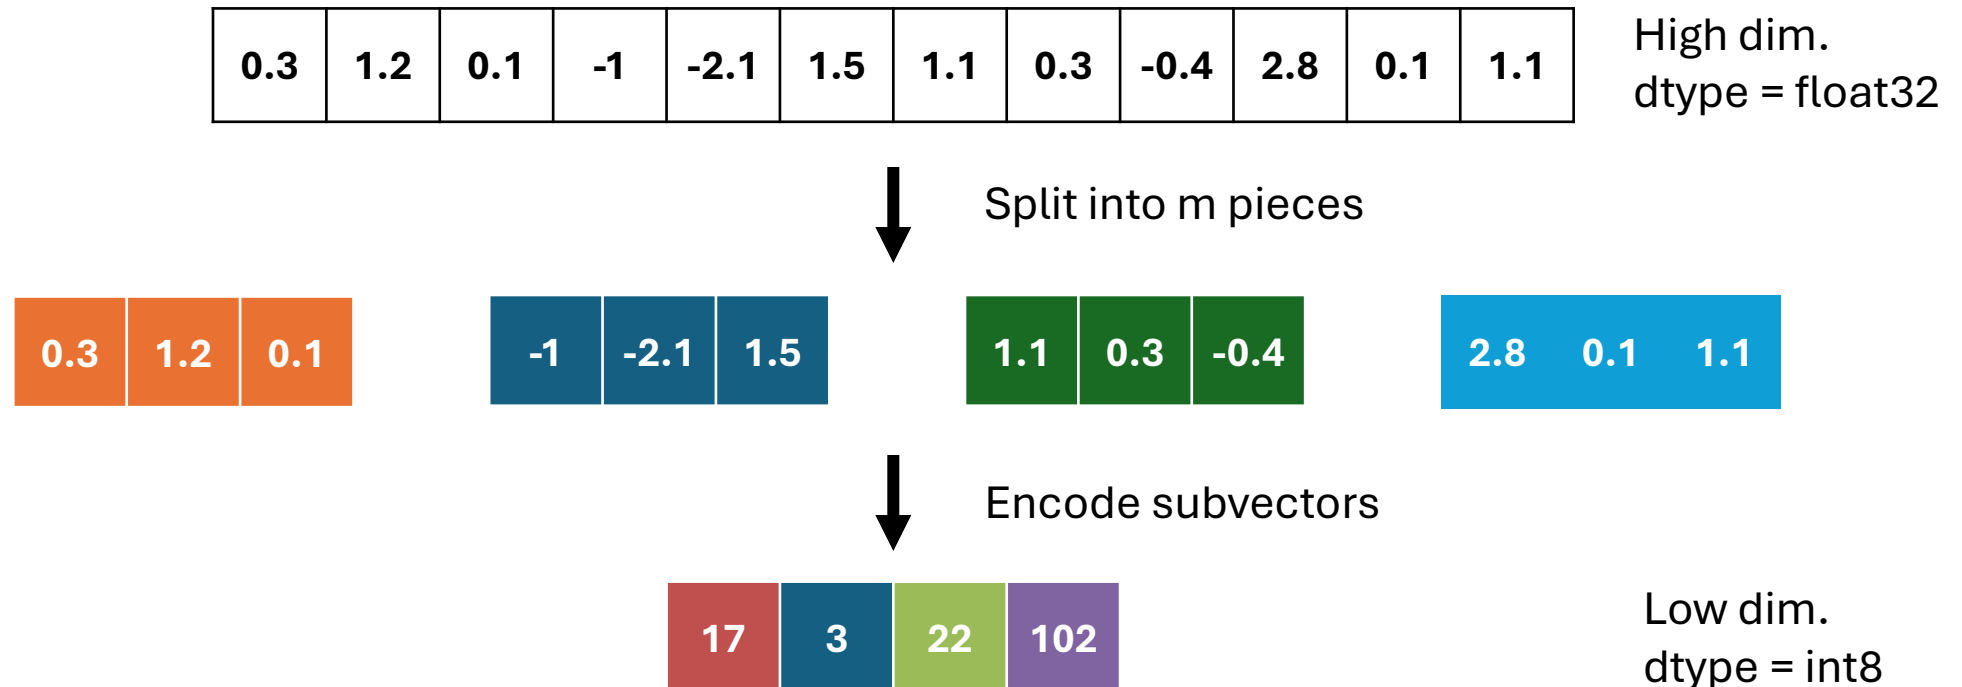

- Compute similarity between query and centroids
  - Select top n clusters
  - Compute similarity to all vectors of these clusters
- 
- Large reduction of search space
  - More overhead

# Indexing Techniques: Product Quantization

---

Main idea: Replace original vector of floats with lower dimensional vector of integers

# Indexing Techniques: Product Quantization

Use k-means clustering on each sub-space

# Indexing Techniques: Product Quantization

Use k-means clustering on each sub-space

# Indexing Techniques: Product Quantization

---

Reduces  $n * d$  (embedding space) matrix of floats to  $n * m$  integers

Additional preprocessing: Store distance from sub-vectors to centroids

Query time:

- Encode query vector in the same way 
- Approximate distance from query to doc by sum of stored distance from doc sub-vector to query cluster centroid

# Indexing Techniques: Product Quantization

---

## Pros:

- Much faster
- Memory efficient

## Cons:

- Results are approximate
- Quality depends on split and clustering parameters

# Indexing Techniques: Graph Indices

---

e.g.: HNSW (Hierarchical Navigable Small Worlds)

- Proximity graph, vectors are linked with similar “friends”
- Search starts at predefined “entry point”, visit “friends” until no nearer vertex is found

# Indexing Techniques: Graph Indices

Search space is split into hierarchical layers

- Top layer has longest distances
- When at a local minimum: drop one layer and keep searching
- Repeat until NN at lowest layer
- Needs additional pre-processing and memory, but scales much better to huge data sets

# Approximate NN Search

---

- Brute-force search does not scale well beyond a couple of million vectors
- Fortunately, nearest neighbor search of vectors is a very common and broadly used technique in ML
  - many techniques and libraries to speed up search
- Popular library: FAISS
  - Offering many algorithms (brute-force, inverted lists on clusters, HNSW, ...)
  - CPU and GPU supported
- Approximate search is another tradeoff between latency-effectiveness
  - We add a lot of complexity to the search system, but necessary for low-latency CPU serving

# Production Support

---

- Dense retrieval is gaining more and more support in production systems
  - HuggingFace model hub gives us a common format to share models
  - Search engine must incorporate indexing & query encoding + provide nearest neighbor search
- Projects include Vespa.ai & Pyserini (integrates with Lucene)
  - Vespa provides deep integration of dense retrieval in common search features, such as filtering on properties
    - Important to filter during search, not after as to avoid empty result lists
  - Pyserini is a project focused on reproducing as many dense retrieval models as possible
    - Including easy hybrid search options between BM25 and DR

# Other Uses for the BERT<sub>DOT</sub> Model

---

- Semantic comparisons of all sorts:
  - Sentence, passage, document similarity -> all compressed into 1 vector
  - Recommendation models
- S-BERT (Sentence transformers) library provides many models & scenarios
  - Based on the HuggingFace transformer library
  - Offers many scenarios and built models out of the box
- Adaptions based on dot-product similarity also allow for multi-modal comparisons
  - For example: Encoding images and text in the same vector-space
